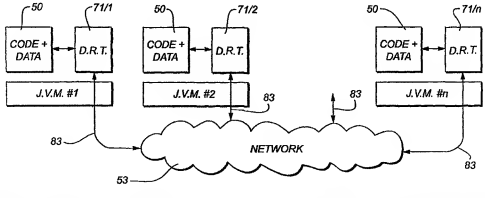
(54) Title: MODIFIED COMPUTER ARCHITECTURE WITH FINALIZATION OF OBJECTS



(57) Abstract: The present invention discloses a modified computer architecture (50, 71, 72) which enables an applications program (50) to be run simultaneously on a plurality of computers (M1, ... Mn). Shared memory at each computer is updated with amendments and/or overwrites so that all memory read requests are satisfied locally. During initial program loading (75), or similar, instructions which result in memory being re-written or manipulated are identified (92). Additional instructions are inserted (103) to cause the equivalent memory locations at all computers to be updated. In particular, the finalization of JAVA language classes and objects is disclosed (162, 163) so finalization only occurs when the last class or object present on all machines is no longer required.

WO 2005/103927 A1

MODIFIED COMPUTER ARCHITECTURE WITH FINALIZATION OF OBJECTS

Field of the Invention

The present invention relates to computers and, in particular, to a modified machine architecture which enables the operation of an application program simultaneously on a plurality of computers interconnected via a communications network.

Background Art

Ever since the advent of computers, and computing, software for computers has been written to be operated upon a single machine. As indicated in Fig. 1, that single prior art machine 1 is made up from a central processing unit, or CPU, 2 which is connected to a memory 3 via a bus 4. Also connected to the bus 4 are various other functional units of the single machine 1 such as a screen 5, keyboard 6 and mouse 7.

A fundamental limit to the performance of the machine 1 is that the data to be manipulated by the CPU 2, and the results of those manipulations, must be moved by the bus 4. The bus 4 suffers from a number of problems including so called bus "queues" formed by units wishing to gain an access to the bus, contention problems, and the like. These problems can, to some extent, be alleviated by various stratagems including cache memory, however, such stratagems invariably increase the administrative overhead of the machine 1.

Naturally, over the years various attempts have been made to increase machine performance. One approach is to use symmetric multiple processors. This prior art approach has been used in so called "super" computers and is schematically indicated in Fig. 2. Here a plurality of CPU's 12 are connected to global memory 13. Again, a bottleneck arises in the communications between the CPU's 12 and the memory 13. This process has been termed "Single System Image". There is only one application and one whole copy of the memory for the application which is distributed over the global memory. The single application can read from and write to, (ie share) any memory location completely transparently.

Where there are a number of such machines interconnected via a network, this is achieved by taking the single application written for a single machine and

partitioning the required memory resources into parts. These parts are then distributed across a number of computers to form the global memory 13 accessible by all CPU's 12. This procedure relies on masking, or hiding, the memory partition from the single running application program. The performance degrades when one CPU on one machine must access (via a network) a memory location physically located in a different machine.

Although super computers have been technically successful in achieving high computational rates, they are not commercially successful in that their inherent complexity makes them extremely expensive not only to manufacture but to administer. In particular, the single system image concept has never been able to scale over "commodity" (or mass produced) computers and networks. In particular, the Single System Image concept has only found practical application on very fast (and hence very expensive) computers interconnected by very fast (and similarly expensive) networks.

A further possibility of increased computer power through the use of a plural number of machines arises from the prior art concept of distributed computing which is schematically illustrated in Fig. 3. In this known arrangement, a single application program (Ap) is partitioned by its author (or another programmer who has become familiar with the application program) into various discrete tasks so as to run upon, say, three machines in which case n in Fig. 3 is the integer 3. The intention here is that each of the machines M1...M3 runs a different third of the entire application and the intention is that the loads applied to the various machines be approximately equal. The machines communicate via a network 14 which can be provided in various forms such as a communications link, the internet, intranets, local area networks, and the like. Typically the speed of operation of such networks 14 is an order of magnitude slower than the speed of operation of the bus 4 in each of the individual machines M1, M2, etc.

Distributed computing suffers from a number of disadvantages. Firstly, it is a difficult job to partition the application and this must be done manually. Secondly, communicating data, partial results, results and the like over the network 14 is an administrative overhead. Thirdly, the need for partitioning makes it extremely

difficult to scale upwardly by utilising more machines since the application having been partitioned into, say three, does not run well upon four machines. Fourthly, in the event that one of the machines should become disabled, the overall performance of the entire system is substantially degraded.

A further prior art arrangement is known as network computing via "clusters" as is schematically illustrated in Fig. 4. In this approach, the entire application is loaded onto each of the machines M1, M2 ....Mn. Each machine communicates with a common database but does not communicate directly with the other machines. Although each machine runs the same application, each machine is doing a different "job" and uses only its own memory. This is somewhat analogous to a number of windows each of which sell train tickets to the public. This approach does operate, is scalable and mainly suffers from the disadvantage that it is difficult to administer the network.

In computer languages such as JAVA and MICROSOFT.NET there are two major types of constructs with which programmers deal. In the JAVA language these are known as objects and classes. Every time an object is created there is an initialization routine run known as "<init>". Similarly, every time a class is loaded there is an initialization routine known as "<clinit>". Other languages use different terms but utilize a similar concept. However, there is no equivalent "clean up" or deletion routine to delete an object or class once it is no longer required. Instead, this "clean up" happens unobtrusively in a background mode.

The present invention discloses a computing environment in which an application program operates simultaneously on a plurality of computers. In such an environment it is necessary to ensure that the "clean up" (or deletion or finalisation) operates in a consistent fashion across all the machines. It is this goal of consistent finalization that is the genesis of the present invention.

In accordance with a first aspect of the present invention there is disclosed a method multiple computer system having at least one application program running simultaneously on a plurality of computers interconnected by a communications network, wherein a like plurality of substantially identical objects are created, each in

the corresponding computer and each having a substantially identical name, and wherein all said identical objects are collectively deleted when each one of said plurality of computers no longer needs to refer to their corresponding object.

In accordance with a second aspect of the present invention there is disclosed a plurality of computers interconnected via a communications link and operating at least one application program simultaneously wherein each said computer in operating said at least one application program needs, or no longer needs to refer to an object only in local memory physically located in each said computer, the contents of the local memory utilized by each said computer is fundamentally similar but not, at each instant, identical, and every one of said computers has a finalization routine which deletes a non-referenced object only if each one of said plurality of computers no longer needs to refer to their corresponding object.

In accordance with a third aspect of the present invention there is disclosed a method of running at least one application program on a plurality of computers simultaneously, said computers being interconnected by means of a communications network, said method comprising the steps of:

(i) creating a like plurality of substantially identical objects each in the corresponding computer and each having a substantially identical name, and

(ii) deleting all said identical objects collectively when all of said plurality of computers no longer need to refer to their corresponding object.

In accordance with a fourth aspect of the present invention there is disclosed a method of ensuring consistent finalization of an application program to be run simultaneously on a plurality of computers interconnected via a communications network, said method comprising the steps of:

(i) scrutinizing said application program at, or prior to, or after loading to detect each program step defining an finalization routine, and

(ii) modifying said finalization routine to ensure collective deletion of corresponding objects in all said computers only when each one of said computers no longer needs to refer to their corresponding object.

In accordance with a fifth aspect of the present invention there is disclosed a method a multiple thread processing computer operation in which individual threads of a single application program are simultaneously being processed each on a corresponding one of a plurality of computers interconnected via a communications link, and in which objects in local memory physically associated with the computer processing each thread have corresponding objects in the local memory of each other said computer, the improvement comprising collectively deleting all said corresponding objects when each one of said plurality of computers no longer needs to refer to their corresponding object.

In accordance with a sixth aspect of the present invention there is disclosed a computer program product comprising a set of program instructions stored in a storage medium and operable to permit a plurality of computers to carry out the abovementioned methods.

Brief Description of the Drawings

Embodiments of the present invention will now be described with reference to the drawings in which:

Fig. 1 is a schematic view of the internal architecture of a conventional computer,

Fig. 2 is a schematic illustration showing the internal architecture of known symmetric multiple processors,

Fig. 3 is a schematic representation of prior art distributed computing,

Fig. 4 is a schematic representation of a prior art network computing using clusters,

Fig. 5 is a schematic block diagram of a plurality of machines operating the same application program in accordance with a first embodiment of the present invention,

Fig. 6 is a schematic illustration of a prior art computer arranged to operate JAVA code and thereby constitute a JAVA virtual machine,

Fig. 7 is a drawing similar to Fig. 6 but illustrating the initial loading of code in accordance with the preferred embodiment,

Fig. 8 is a drawing similar to Fig. 5 but illustrating the interconnection of a plurality of computers each operating JAVA code in the manner illustrated in Fig. 7,

Fig. 9 is a flow chart of the procedure followed during loading of the same application on each machine in the network,

Fig. 10 is a flow chart showing a modified procedure similar to that of Fig. 9,

Fig. 11 is a schematic representation of multiple thread processing carried out on the machines of Fig. 8 utilizing a first embodiment of memory updating,

Fig. 12 is a schematic representation similar to Fig. 11 but illustrating an alternative embodiment,

Fig. 13 illustrates multi-thread memory updating for the computers of Fig. 8,

Fig. 14 is a schematic illustration of a prior art computer arranged to operate in JAVA code and thereby constitute a JAVA virtual machine,

Fig. 15 is a schematic representation of n machines running the application program and serviced by an additional server machine X,

Fig. 16 is a flow chart of illustrating the modification of "clean up" or finalization routines,

Fig. 17 is a flow chart illustrating the continuation or abortion of finalization routines,

Fig. 18 is a flow chart illustrating the enquiry sent to the server machine X,

Fig. 19 is a flow chart of the response of the server machine X to the request of Fig. 18,

Fig. 20 is a schematic representation of two laptop computers interconnected to simultaneously run a plurality of applications, with both applications running on a single computer,

Fig. 21 is a view similar to Fig. 20 but showing the Fig. 20 apparatus with one application operating on each computer, and

Fig. 22 is a view similar to Figs. 20 and 21 but showing the Fig. 20 apparatus with both applications operating simultaneously on both computers.

The specification includes Annexures A and C which provide actual code fragments which implement various aspects of the described embodiments. Annexure A relates to fields and Annexure C to finalization.

Detailed Description

In connection with Fig. 5, in accordance with a preferred embodiment of the present invention a single application program 50 can be operated simultaneously on a number of machines M1, M2...Mn communicating via network 53. As it will become apparent hereafter, each of the machines M1, M2...Mn operates with the same application program 50 on each machine M1, M2...Mn and thus all of the machines M1, M2...Mn have the same application code and data 50. Similarly, each of the machines M1, M2...Mn operates with the same (or substantially the same) modifier 51 on each machine M1, M2...Mn and thus all of the machines M1, M2...Mn have the same (or substantially the same) modifier 51 with the modifier of machine M2 being designated 51/2. In addition, during the loading of, or preceding the execution of, the application 50 on each machine M1, M2...Mn, each application 50 has been modified by the corresponding modifier 51 according to the same rules (or substantially the same rules since minor optimising changes are permitted within each modifier 51/1 ...51/n).

As a consequence of the above described arrangement, if each of the machines M1, M2...Mn has, say, a shared memory capability of 10MB, then the total shared memory available to each application 50 is not, as one might expect, 10n MB but rather only 10MB. However, how this results in improved operation will become apparent hereafter. Naturally, each machine M1, M2...Mn has an unshared memory capability. The unshared memory capability of the machines M1, M2...Mn are normally approximately equal but need not be.

It is known from the prior art to operate a machine (produced by one of various manufacturers and having an operating system operating in one of various different languages) in a particular language of the application, by creating a virtual machine as schematically illustrated in Fig. 6. The prior art arrangement of Fig. 6 takes the form of the application 50 written in the Java language and executing within a Java Virtual Machine 61. Thus, where the intended language of the application is the language JAVA, a JAVA virtual machine is created which is able to operate code in JAVA irrespective of the machine manufacturer and internal details of the machine. For further details see "The JAVA Virtual Machine Specification" 2nd Edition by T. Lindholm & F. Yellin of Sun Microsystems Inc. of the USA.

This well known prior art arrangement of Fig. 6 is modified in accordance with the preferred embodiment of the present invention by the provision of an additional facility which is conveniently termed "distributed run time" or DRT 71 as seen in Fig. 7. In Fig. 7, the application 50 is loaded onto the Java Virtual Machine 72 via the distributed runtime system 71 through the loading procedure indicated by arrow 75. A distributed run time system is available from the Open Software Foundation under the name of Distributed Computing Environment (DCE). In particular, the distributed runtime 71 comes into operation during the loading procedure indicated by arrow 75 of the JAVA application 50 so as to initially create the JAVA virtual machine 72. The sequence of operations during loading will be described hereafter in relation to Fig. 9.

Fig. 8 shows in modified form the arrangement of Fig. 5 utilising JAVA virtual machines, each as illustrated in Fig. 7. It will be apparent that again the same application 50 is loaded onto each machine M1, M2...Mn. However, the communications between each machine M1, M2...Mn, and indicated by arrows 83, although physically routed through the machine hardware, are controlled by the individual DRT's 71/1...71/n within each machine. Thus, in practice this may be conceptionalised as the DRT's 71/1...71/n communicating with each other via the network 73 rather than the machines M1, M2...Mn themselves.

Turning now to Figs. 7 and 9, during the loading procedure 75, the program 50 being loaded to create each JAVA virtual machine 72 is modified. This modification commences at 90 in Fig. 9 and involves the initial step 91 of detecting all memory locations (termed fields in JAVA - but equivalent terms are used in other languages) in the application 50 being loaded. Such memory locations need to be identified for subsequent processing at steps 92 and 93. The DRT 71 during the loading procedure 75 creates a list of all the memory locations thus identified, the JAVA fields being listed by object and class. Both volatile and synchronous fields are listed.

The next phase (designated 92 in Fig. 9) of the modification procedure is to search through the executable application code in order to locate every processing activity that manipulates or changes field values corresponding to the list generated at step 91 and thus writes to fields so the value at the corresponding memory location is

changed. When such an operation (typically putstatic or putfield in the JAVA language) is detected which changes the field value, then an "updating propagation routine" is inserted by step 93 at this place in the program to ensure that all other machines are notified that the value of the field has changed. Thereafter, the loading procedure continues in a normal way as indicated by step 94 in Fig. 9.

An alternative form of initial modification during loading is illustrated in Fig. 10. Here the start and listing steps 90 and 91 and the searching step 92 are the same as in Fig. 9. However, rather than insert the "updating propagation routine" as in step 93 in which the processing thread carries out the updating, instead an "alert routine" is inserted at step 103. The "alert routine" instructs a thread or threads not used in processing and allocated to the DRT, to carry out the necessary propagation. This step 103 is a quicker alternative which results in lower overhead.

Once this initial modification during the loading procedure has taken place, then either one of the multiple thread processing operations illustrated in Figs. 11 and 12 takes place. As seen in Fig. 11, multiple thread processing 110 on the machines consisting of threads 111/1...111/4 is occurring and the processing of the second thread 111/2 (in this example) results in that thread 111/2 becoming aware at step 113 of a change of field value. At this stage the normal processing of that thread 111/2 is halted at step 114, and the same thread 111/2 notifies all other machines M2...Mn via the network 53 of the identity of the changed field and the changed value which occurred at step 113. At the end of that communication procedure, the thread 111/2 then resumes the processing at step 115 until the next instance where there is a change of field value.

In the alternative arrangement illustrated in Fig. 12, once a thread 121/2 has become aware of a change of field value at step 113, it instructs DRT processing 120 (as indicated by step 125 and arrow 127) that another thread(s) 121/1 allocated to the DRT processing 120 is to propagate in accordance with step 128 via the network 53 to all other machines M2...Mn the identity of the changed field and the changed value detected at step 113. This is an operation which can be carried out quickly and thus the processing of the initial thread 111/2 is only interrupted momentarily as indicated in step 125 before the thread 111/2 resumes processing in step 115. The other thread

121/1 which has been notified of the change (as indicated by arrow 127) then communicates that change as indicated in step 128 via the network 53 to each of the other machines M2...Mn.

This second arrangement of Fig. 12 makes better utilisation of the processing power of the various threads 111/1...111/3 and 121/1 (which are not, in general, subject to equal demands) and gives better scaling with increasing size of "n", (n being an integer greater than or equal to 2 which represents the total number of machines which are connected to the network 53 and which run the application program 50 simultaneously). Irrespective of which arrangement is used, the changed field and identities and values detected at step 113 are propagated to all the other machines M2...Mn on the network.

This is illustrated in Fig. 13 where the DRT 71/1 and its thread 121/1 of Fig. 12 (represented by step 128 in Fig. 13) sends via the network 53 the identity and changed value of the listed memory location generated at step 113 of Fig. 12 by processing in machine M1, to each of the other machines M2...Mn.

Each of the other machines M2...Mn carries out the action indicated by steps 135 and 136 in Fig. 13 for machine Mn by receiving the identity and value pair from the network 53 and writing the new value into the local corresponding memory location.

In the prior art arrangement in Fig. 3 utilising distributed software, memory accesses from one machine's software to memory physically located on another machine are permitted by the network interconnecting the machines. However, such memory accesses can result in delays in processing of the order of $10^6 - 10^7$ cycles of the central processing unit of the machine. This in large part accounts for the diminished performance of the multiple interconnected machines.

However, in the present arrangement as described above in connection with Fig. 8, it will be appreciated that all reading of data is satisfied locally because the current value of all fields is stored on the machine carrying out the processing which generates the demand to read memory. Such local processing can be satisfied within

$10^2 - 10^3$ cycles of the central processing unit. Thus, in practice, there is substantially no waiting for memory accesses which involves reads.

However, most application software reads memory frequently but writes to memory relatively infrequently. As a consequence, the rate at which memory is being written or re-written is relatively slow compared to the rate at which memory is being read. Because of this slow demand for writing or re-writing of memory, the fields can be continually updated at a relatively low speed via the inexpensive commodity network 53, yet this low speed is sufficient to meet the application program's demand for writing to memory. The result is that the performance of the Fig. 8 arrangement is vastly superior to that of Fig. 3.

In a further modification in relation to the above, the identities and values of changed fields can be grouped into batches so as to further reduce the demands on the communication speed of the network 53 interconnecting the various machines.

It will also be apparent to those skilled in the art that in a table created by each DRT 71 when initially recording the fields, for each field there is a name or identity which is common throughout the network and which the network recognises. However, in the individual machines the memory location corresponding to a given named field will vary over time since each machine will progressively store changed field values at different locations according to its own internal processes. Thus the table in each of the DRTs will have, in general, different memory locations but each global "field name" will have the same "field value" stored in the different memory locations.

It will also be apparent to those skilled in the art that the abovementioned modification of the application program during loading can be accomplished in up to five ways by:

(i) re-compilation at loading,

(ii) by a pre-compilation procedure prior to loading,

(iii) compilation prior to loading,

(iv) a "just-in-time" compilation, or

(v) re-compilation after loading (but, or for example, before execution of the relevant or corresponding application code in a distributed environment).

Traditionally the term "compilation" implies a change in code or language, eg from source to object code or one language to another. Clearly the use of the term "compilation" (and its grammatical equivalents) in the present specification is not so restricted and can also include or embrace modifications within the same code or language.

In the first embodiment, a particular machine, say machine M2, loads the application code on itself, modifies it, and then loads each of the other machines M1, M3 ... Mn (either sequentially or simultaneously) with the modified code. In this arrangement, which may be termed "master/slave", each of machines M1, M3, ... Mn loads what it is given by machine M2.

In a still further embodiment, each machine receives the application code, but modifies it and loads the modified code on that machine. This enables the modification carried out by each machine to be slightly different being optimized based upon its architecture and operating system, yet still coherent with all other similar modifications.

In a further arrangement, a particular machine, say M1, loads the unmodified code and all other machines M2, M3 ... Mn do a modification to delete the original application code and load the modified version.

In all instances, the supply can be branched (ie M2 supplies each of M1, M3, M4, etc directly) or cascaded or sequential (ie M2 applies M1 which then supplies M3 which then supplies M4, and so on).

In a still further arrangement, the machines M1 to Mn, can send all load requests to an additional machine (not illustrated) which is not running the application program, which performs the modification via any of the aforementioned methods, and returns the modified routine to each of the machines M1 to Mn which then load the modified routine locally. In this arrangement, machines M1 to Mn forward all load requests to this additional machine which returns a modified routine to each

machine. The modifications performed by this additional machine can include any of the modifications covered under the scope of the present invention.

Persons skilled in the computing arts will be aware of at least four techniques used in creating modifications in computer code. The first is to make the modification in the original (source) language. The second is to convert the original code (in say JAVA) into an intermediate representation (or intermediate language). Once this conversion takes place the modification is made and then the conversion is reversed. This gives the desired result of modified JAVA code.

The third possibility is to convert to machine code (either directly or via the abovementioned intermediate language). Then the machine code is modified before being loaded and executed. The fourth possibility is to convert the original code to an intermediate representation, which is then modified and subsequently converted into machine code.

The present invention encompasses all four modification routes and also a combination of two, three or even all four, of such routes.

Turning now to Fig. 14, there is illustrated a schematic representation of a single prior art computer operated as a JAVA virtual machine. In this way, a machine (produced by any one of various manufacturers and having an operating system operating in any one of various different languages) can operate in the particular language of the application program 50, in this instance the JAVA language. That is, a JAVA virtual machine 72 is able to operate code 50 in the JAVA language, and utilize the JAVA architecture irrespective of the machine manufacturer and the internal details of the machine.

In the JAVA language, the initialization routine <clinit> happens only once when a given class file 50A is loaded. However, the initialization routine <init> happens often, for example every time a new object 50X, 50Y or 50Z is created. In addition, classes are loaded prior to objects so that in the application program illustrated in Fig. 14, having a single class 50A and three objects 50X-50Z, the first

class 50A is loaded first, then first object 50X is loaded, then second object 50Y is loaded and finally third object 50Z is loaded. Where, as in Fig. 14, there is only a single computer or machine 72, then no conflict or inconsistency arises in the running of the initialization routines intended to operate during the loading procedure because for conventional operation each initialization routine is executed only once.

Furthermore, the single machine of Fig. 14 is able to easily keep track of whether the specific objects 50X-50Z are, in future, liable to be required for the program 50. This is done by maintaining a "handle count" or similar. This count keeps track of the number of places in the executable code where reference is made to a specific object. When the handle count for a specific object reaches zero, there is nowhere in the executable code which makes reference to the object. The object is then said to be "finalizable".

Once this state has been achieved, the object can be safely deleted (or cleaned up or finalized) because it is no longer needed. The same procedure applies mutatis mutandis for classes. In particular, the computer programmer when writing a program using the JAVA language and architecture, need not write any specific code in order to provide for this cleaning up, deletion or finalization. Instead a single JAVA virtual machine 72 can keep track of the class and object handle counts and clean up (or carry out finalization) as necessary in an unobtrusive fashion.

However, in the arrangement illustrated in Fig. 8, (and also in Figs. 20-22), a plurality of individual computers or machines M1, M2 ..... Mn are provided each of which are interconnected via a communications network 53 and each of which is provided with a modifier 51 (as in Fig. 5 and realised by the DRT 71 of Fig. 8) and loaded with a common application program 50. Essentially the modifier 51 or DRT 71 modifies the application code 50 to execute clean up routines across the plurality of individual machines M1, M2...Mn. It follows therefore that in such a computing environment it is necessary to ensure that each of the individual machines is finalized in a consistent fashion (with respect to the others).

In particular, whilst one particular machine (say, M3) may have no further call on an object or class, another machine (say M5) may still need to refer to that object or class in future. Thus if the object or class were to be deleted from machine M3, then if M5 were to write to that object and amend its value, then that change in value could not be propagated throughout all the machines M1, M2...Mn since the machine M3 would not include the relevant object in its local memory. Furthermore, were machine M3 to execute the cleanup routine on a given object or class, the cleanup routine would preform cleanup not just for that object on that machine, but all peer-objects on all other machines as well. Thus invalidating the object on machine M5. Thus the goal of substantially identical memory contents for each of the machines M1, M2...Mn, as required for simultaneous operation of the same application program, would not be achieved.

In order to ensure consistent finalization, or clean up, the application program 50 is scrutinized in order to detect program steps which define a clean up routine. This scrutiny can take place either prior to loading, or during the loading procedure, or even after the loading procedure (but before execution of the relevant corresponding portion of the application code 50). It may be likened to a compilation procedure with the understanding that the term compilation normally involves a change in code or language, eg from source to object code or one language to another. However, in the present instance the term "compilation" (and its grammatical equivalents) is not so restricted and can also include embrace modifications within the same code or language.

As a consequence, in the abovementioned scrutiny clean up routines are initially looked for, and when found a modifying code is inserted so as to give rise to a modified clean up routine. This modified routine is to abort the clean up routine on any specific machine unless the class or object to be deleted is marked for deletion by all other machines. There are several different modes whereby this modification and loading can be carried out.

Thus, in one mode, the DRT 71/1 on the loading machine, in this example JVM#1, asks the DRT's 71/2...71/n of all the other machines M2...Mn if the first object 50X, say, is utilized (ie not marked for deletion) by any other machine

M2...Mn. If the answer to this question is yes, then the normal clean up procedure is turned off or disabled for the first object 50X on machine JVM#1. If the answer is no, (ie the first object 50X is marked for deletion on all other machines) then the normal clean up procedure is operated and the first object 50X is deleted not only on machine JVM#1 but on all other machines M2...Mn. Preferably the clean up task is allocated to the last machine M1 marking the object or class for deletion.

As seen in Fig. 15 a modification to the general arrangement of Fig. 8 is provided in that machines M1, M2...Mn are as before and run the same application program 50 (or programmes) on all machines M1, M2...Mn simultaneously. However, the previous arrangement is modified by the provision of a server machine X which is conveniently able to supply housekeeping functions, for example, and especially the clean up of structures, assets and resources. Such a server machine X can be a low value commodity computer such as a PC since its computational load is low. As indicated by broken lines in Fig. 15, two server machines X and X+1 can be provided for redundancy purposes to increase the overall reliability of the system. Where two such server machines X and X+1 are provided, they are preferably operated as dual machines in a cluster.

It is not necessary to provide a server machine X as its computational load can be distributed over machines M1, M2...Mn. Alternatively, a database operated by one machine (in a master/slave type operation) can be used for the housekeeping function(s).

Fig. 16 shows a preferred general procedure to be followed. After loading 161 has been commenced, the instructions to be executed are considered in sequence and all clean up routines are detected as indicated in step 162. In the JAVA language these are the "finalize( )" routine (or method in JAVA terminology). Other languages use different terms.

Where a clean up routine is detected, it is modified at step 163, typically by inserting further instructions into the routine. Alternatively, the modifying instructions could be inserted prior to the routine. Once the modification has been completed the loading procedure continues, as indicated in step 164.

Fig. 17 illustrates a particular form of modification. Firstly, the structures, assets or resources (in JAVA termed classes or objects) 50A, 50X...50Y which are possible candidates to be cleaned up, have already been allocated a name or tag which can be used globally by all machines M1, M2...Mn, as indicated by step 172. This preferably happens when the classes or objects are originally initialized. This is most conveniently done via a table maintained by server machine X. This table also includes the "clean up status" of the class or object. In the preferred embodiment, this table also includes a counter which stores a count of the number of machines which have marked this asset for deletion. Thus a total count value of less than (n-1) indicates a "do not clean up" status for the asset as a network whole.

As indicated in Fig. 17, if the global name is not marked for deletion on all other machines (ie all except on the machine proposing to carry out the clean up routine) then this means that the proposed clean up routine of the object or class should be aborted since the object or class is still required, as indicated by step 175.

However, if the global name is marked for deletion on all machines, this means that no other machine requires this class or object. As a consequence, the regular clean up routine indicated in step 176 can be, and should be, carried out.

Fig. 18 shows the enquiry made by the machine proposing to execute a clean up routine (one of M1, M2...Mn) to the server machine X. The operation of this proposing machine is temporarily interrupted, as shown in step 181 and 182, until the reply is received from machine X, indicated by step 182.

Fig. 19 shows the activity carried out by machine X in response to such an enquiry. The clean up status is determined as seen in step 192 and, if no - the named resource is not marked for deletion on (n-1) machines (ie is utilized elsewhere), the response to that effect is sent to the enquiring machine 194 but the "marked for deletion" counter is incremented by one (1), as shown by step 197. Similarly, if the answer is yes - the corresponding reply is sent as indicated by steps 195. The waiting enquiring machine 182 is then able to respond accordingly. As indicated by broken lines in Fig. 19, preferably in addition to the yes response shown in step 195, the shared table is updated so that the status of the globally named asset is changed to "cleaned up" as indicated by step 196.

Reference is made to the accompanying Annexure C in which:
Annexure C1 is a typical code fragment from an unmodified finalize routine,
Annexure C2 is an equivalent in respect of a modified finalize routine, and
Annexure C3 is an equivalent in respect of a modified finalize routine.

Annexures C1 and C2 are the before and after excerpt of a finalize routine respectively. The modified code that is added to the method is highlighted in bold. In the original code sample of Annexure C1, the finalize method prints "Deleted..." to the computer console on event of finalization (ie deletion) of this object. Thus, without management of object finalization in a distributed environment, each machine would re-finalize the same object, thus executing the finalize method more than once for a single globally-named object. Clearly this is not what the programmer of the application program expects to happen.

So, taking advantage of the DRT, the application code is modified as it is loaded into the machine by changing the finalize method. The changes made (highlighted in bold) are the initial instructions that the finalize method executes. These added instructions check if this object is the last remaining object reference by calling the isLastReference() method, which returns either true or false corresponding to whether or not this object on this machine is the last of the peer objects to request finalization.

The isLastReference() method of the DRT can optionally take an argument which represents a unique identifier for this object (See Annexure C3), for example the name of the object, a reference to the object in question, or a unique number representing this object across all nodes, to be used in the determination of the finalization status of this class. This way, the DRT can support the finalization of multiple objects at the same time without becoming confused as to which of the multiple objects are already finalized and which are not, by using the unique identifier of each object to consult the correct record in the finalization table.

The DRT can determine the finalization state of the object in a number of ways. Preferably, it can ask each machine in turn if their local copy of this object has

been marked for finalization, and if any machine replies false, then return true, otherwise false. Alternatively, the DRT on the local machine can consult a shared record table (perhaps on a separate machine (eg machine X), or a coherent shared record table on the local machine, or a database) to determine if this object has been marked for finalization by all machines except the current machine.

If the DRT returns false then this means that this object has been marked for finalization on all other machine in the distributed environment, and hence, the execution of the original finalize code-block is to proceed as this is considered the last remaining object reference.

On the other hand, if the DRT returns true, then this means that this object has not been marked for finalization by all other machines in the distributed environment, as recorded in the shared record table of finalized objects. In such a case, the original code block is **NOT** to be executed, as it will potentially invalidate the object on those machine(s) that are continuing to use the object and have yet to mark this object for finalization. Thus, when the DRT returns true, the inserted three instructions prevent execution of the original code, and return straight away to the application program.

Given the fundamental concept of testing to see a clean up is ready to be carried out, and if so carrying it out, and if not, not carrying it out, there are several different ways in which this concept can be implemented.

In the first embodiment, a particular machine, say machine M2, loads the clean up on itself, modifies it, and then loads each of the other machines M1, M3 ... Mn (either sequentially or simultaneously) with the modified routine. In this arrangement, which may be termed "master/slave" each of machines M1, M3, ... Mn loads what it is given by machine M2.

In a variation of this "master/slave" arrangement, machine M2 loads the clean up routine in unmodified form on machine M2 and then on the other machines deletes the clean up routine in its entirety and loads the modified code. Thus in this instance

the modification is not a by-passing of the clean up routine but a deletion of it on all machines except one.

In a still further embodiment, each machine receives the clean up routine, but modifies it and loads the modified routine on that machine. This enables the modification carried out by each machine to be slightly different being optimized based upon its architecture and operating system, yet still coherent with all other similar modifications.

In a further arrangement, a particular machine, say M1, loads the unmodified clean up routine and all other machines M2, M3 ... Mn do a modification to delete the original clean up routine and load the modified version.

In all instances, the supply can be branched (ie M2 supplies each of M1, M3, M4, etc directly) or cascaded or sequential (ie M2 applies M1 which then supplies M3 which then supplies M4, and so on).

In a still further arrangement, the machines M1 to Mn, can send all load requests to an additional machine X (of Fig. 15), which performs the modification via any of the afore mentioned methods, and returns the modified routine to each of the machines M1 to Mn which then load the modified routine locally. In this arrangement, machines M1 to Mn forward all load requests to machine X, which returns a modified routine to each machine. The modifications performed by machine X can include any of the modifications covered under the scope of the present invention.

Persons skilled in the computing arts will be aware of four techniques used in creating modifications in computer code. The first is to make the modification in the original (source) language. The second is to convert the original code (in say JAVA) into an intermediate representation (or intermediate language). Once this conversion takes place the modification is made and then the conversion is reversed. This gives the desired result of modified JAVA code.

The third possibility is to convert to machine code (either directly or via the abovementioned intermediate language). Then the machine code is modified before being loaded and executed. The fourth possibility is to convert the original code to an intermediate representation, which is then modified and subsequently converted into machine code.

The present invention encompasses all four modification routes and also a combination of two, three or even all four, of such routes.

Turning now to Figs. 20-22, two laptop computers 101 and 102 are illustrated. The computers 101 and 102 are not necessarily identical and indeed, one can be an IBM or IBM-clone and the other can be an APPLE computer. The computers 101 and 102 have two screens 105, 115 two keyboards 106, 116 but a single mouse 107. The two machines 101, 102 are interconnected by a means of a single coaxial cable or twisted pair cable 314.

Two simple application programs are downloaded onto each of the machines 101, 102, the programs being modified as they are being loaded as described above. In this embodiment the first application is a simple calculator program and results in the image of a calculator 108 being displayed on the screen 105. The second program is a graphics program which displays four coloured blocks 109 which are of different colours and which move about at random within a rectangular box 310. Again, after loading, the box 310 is displayed on the screen 105. Each application operates independently so that the blocks 109 are in random motion on the screen 105 whilst numerals within the calculator 108 can be selected (with the mouse 107) together with a mathematical operator (such as addition or multiplication) so that the calculator 108 displays the result.

The mouse 107 can be used to "grab" the box 310 and move same to the right across the screen 105 and onto the screen 115 so as to arrive at the situation illustrated in Fig. 21. In this arrangement, the calculator application is being conducted on machine 101 whilst the graphics application resulting in display of box 310 is being conducted on machine 102.

However, as illustrated in Fig. 22, it is possible by means of the mouse 107 to drag the calculator 108 to the right as seen in Fig. 21 so as to have a part of the calculator 108 displayed by each of the screens 105, 115. Similarly, the box 310 can be dragged by means of the mouse 107 to the left as seen in Fig. 21 so that the box 310 is partially displayed by each of the screens 105, 115 as indicated Fig. 22. In this configuration, part of the calculator operation is being performed on machine 101 and part on machine 102 whilst part of the graphics application is being carried out the machine 101 and the remainder is carried out on machine 102.

The foregoing describes only some embodiments of the present invention and modifications, obvious to those skilled in the art, can be made thereto without departing from the scope of the present invention. For example, reference to JAVA includes both the JAVA language and also JAVA platform and architecture.

Those skilled in the programming arts will be aware that when additional code or instructions is/are inserted into an existing code or instruction set to modify same, the existing code or instruction set may well require further modification (eg by re-numbering of sequential instructions) so that offsets, branching, attributes, mark up and the like are catered for.

Similarly, in the JAVA language memory locations include, for example, both fields and array types. The above description deals with fields and the changes required for array types are essentially the same mutatis mutandis. Also the present invention is equally applicable to similar programming languages (including procedural, declarative and object orientated) to JAVA including Micrsoft.NET platform and architecture (Visual Basic, Visual C/C^{++}, and C#) FORTRAN, C/C^{++}, COBOL, BASIC etc.

The abovementioned embodiment in which the code of the JAVA finalisation or clean up routine is modified, is based upon the assumption that either the run time system (say, JAVA HOTSPOT VIRTUAL MACHINE written in C and JAVA) or the operating system (LINUX written in C and Assembler, for example) of each machine M1…Mn will call the JAVA finalisation routine. It is possible to leave the JAVA finalisation routine unamended and instead amend the LINUX or HOTSPOT routine which calls the JAVA finalisation routine, so that if the object or class is not to

be deleted, then the JAVA finalisation routine is not called. In order to embrace such an arrangement the term "finalisation routine" is to be understood to include within its scope both the JAVA finalisation routine and the "combination" of the JAVA finalisation routine and the LINUX or HOTSPOT code fragments which call or initiate the JAVA finalisation routine.

The terms object and class used herein are derived from the JAVA environment and are intended to embrace similar terms derived from different environments such as dynamically linked libraries (DLL), or object code packages, or function unit or memory locations.

The term "comprising" (and its grammatical variations) as used herein is used in the inclusive sense of "having" or "including" and not in the exclusive sense of "consisting only of".

Annexure A

The following are program listings in the JAVA language:

A1. This first excerpt is part of the modification code. It searches through the code array, and when it finds a putstatic instruction (opcode 178), it implements the modifications.

```
// START
byte[] code =  Code_attribute.code;      // Bytecode of a given method in a
                                         // given classfile.

int code_length = Code_attribute.code_length;

int DRT = 99;        // Location of the CONSTANT_Methodref_info for the
                     // DRT.alert() method.

for (int i=0; i<code_length; i++){

   if ((code[i] & 0xff) == 179){ // Putstatic instruction.

      System.arraycopy(code, i+3, code, i+6, code_length-(i+3));

      code[i+3] = (byte) 184;     // Invokestatic instruction for the
                                  // DRT.alert() method.

      code[i+4] = (byte) ((DRT >>> 8) & 0xff);

      code[i+5] = (byte) (DRT & 0xff);

   }

}
// END
```

A2. This second excerpt is part of the DRT.alert() method. This is the body of the DRT.alert() method when it is called.

```
// START
public static void alert(){

   synchronized (ALERT_LOCK){

      ALERT_LOCK.notify(); // Alerts a waiting DRT thread in the background.

   }

}
// END
```

A3. This third excerpt is part of the DRT Sending. This code fragment shows the DRT in a separate thread, after being notified, sending the value across the network.

```
// START
MulticastSocket ms = DRT.getMulticastSocket();        // The multicast socket
                                                      // used by the DRT for
                                                      // communication.

byte nameTag = 33;          // This is the "name tag" on the network for this
                            // field.
```

```
Field field = modifiedClass.getDeclaredField("myField1");   // Stores
                                                            // the field
                                                            // from the
                                                            // modified
                                                            // class.

// In this example, the field is a byte field.
while (DRT.isRunning()){

   synchronized (ALERT_LOCK){

      ALERT_LOCK.wait();   // The DRT thread is waiting for the alert
                           // method to be called.

      byte[] b = new byte[]{nameTag, field.getByte(null)};  // Stores
                                                            // the
                                                            // nameTag
                                                            // and the
                                                            // value
                                                            // of the
                                                            // field from
                                                            // the modified
                                                            // class in a
                                                            // buffer.

      DatagramPacket dp = new DatagramPacket(b, 0, b.length);

      ms.send(dp);  // Send the buffer out across the network.

   }

}
// END
```

A4. The fourth excerpt is part of the DRT receiving. This is a fragment of code to receive a DRT sent alert over the network.

```
// START
MulticastSocket ms = DRT.getMulticastSocket(); // The multicast socket
                                               // used by the DRT for
                                               // communication.

DatagramPacket dp = new DatagramPacket(new byte[2], 0, 2);

byte nameTag = 33;          // This is the "name tag" on the network for this
                            // field.

Field field = modifiedClass.getDeclaredField("myField1");   // Stores the
                                                            // field from
                                                            // the modified
                                                            // class.

// In this example, the field is a byte field.
while (DRT.isRunning){

   ms.receive(dp);  // Receive the previously sent buffer from the network.

   byte[] b = dp.getData();

   if (b[0] == nameTag){   // Check the nametags match.
      field.setByte(null, b[1]); // Write the value from the network packet
                                 // into the field location in memory.

   }
```

```
}
// END
```

A5. The fifth excerpt is an example application before modification has occurred.

```
Method void setValues(int, int)
  0 iload_1
  1 putstatic #3 <Field int staticValue>
  4 aload_0
  5 iload_2
  6 putfield #2 <Field int instanceValue>
  9 return
```

A6. The sixth excerpt is the same example application in 5 after modification has been performed. The modifications are highlighted in **bold.**

```
Method void setValues(int, int)
  0 iload_1
  1 putstatic #3 <Field int staticValue>
  4 ldc #4 <String "example">
  6 iconst_0
  7 invokestatic #5 <Method void alert(java.lang.Object, int)>
 10 aload_0
 11 iload_2
 12 putfield #2 <Field int instanceValue>
 15 aload_0
 16 iconst_1
 17 invokestatic #5 <Method void alert(java.lang.Object, int)>
 20 return
```

A7. The seventh excerpt is the source-code of the example application used in excerpt 5 and 6.

```
import java.lang.*;

public class example{

   /** Shared static field. */
   public static int staticValue = 0;

   /** Shared instance field. */
   public int instanceValue = 0;

   /** Example method that writes to memory (instance field). */
   public void setValues(int a, int b){

      staticValue = a;

      instanceValue = b;

   }

}
```

A8. The eighth excerpt is the source-code of FieldAlert, which alerts the "distributed run-time" to propagate a changed value.

```
import java.lang.*;
import java.util.*;
import java.net.*;
import java.io.*;

public class FieldAlert{

   /** Table of alerts. */
   public final static Hashtable alerts = new Hashtable();

   /** Object handle. */
   public Object reference = null;

   /** Table of field alerts for this object. */
   public boolean[] fieldAlerts = null;

   /** Constructor. */
   public FieldAlert(Object o, int initialFieldCount){
      reference = o;
      fieldAlerts = new boolean[initialFieldCount];
   }

   /** Called when an application modifies a value. (Both objects and
       classes) */
   public static void alert(Object o, int fieldID){

      // Lock the alerts table.
      synchronized (alerts){

         FieldAlert alert = (FieldAlert) alerts.get(o);

         if (alert == null){      // This object hasn't been alerted already,
                                  // so add to alerts table.
            alert = new FieldAlert(o, fieldID + 1);
            alerts.put(o, alert);
         }

         if (fieldID >= alert.fieldAlerts.length){
            // Ok, enlarge fieldAlerts array.
            boolean[] b = new boolean[fieldID+1];
            System.arraycopy(alert.fieldAlerts, 0, b, 0,
              alert.fieldAlerts.length);
            alert.fieldAlerts = b;
         }

         // Record the alert.
         alert.fieldAlerts[fieldID] = true;

         // Mark as pending.
         FieldSend.pending = true;       // Signal that there is one or more
                                         // propagations waiting.

         // Finally, notify the waiting FieldSend thread(s)
         if (FieldSend.waiting){
            FieldSend.waiting = false;
            alerts.notify();
         }
```

```
        }

    }

}
```

A9. The ninth excerpt is the source-code of FieldSend, which propagates changes values alerted to it via FieldAlert.

```
import java.lang.*;
import java.lang.reflect.*;
import java.util.*;
import java.net.*;
import java.io.*;

public class FieldSend implements Runnable{

    /** Protocol specific values. */
    public final static int CLOSE = -1;
    public final static int NACK = 0;
    public final static int ACK = 1;
    public final static int PROPAGATE_OBJECT = 10;
    public final static int PROPAGATE_CLASS = 20;

    /** FieldAlert network values. */
    public final static String group =
       System.getProperty("FieldAlert_network_group");
    public final static int port =
       Integer.parseInt(System.getProperty("FieldAlert_network_port"));

    /** Table of global ID's for local objects. (hashcode-to-globalID
        mappings) */
    public final static Hashtable objectToGlobalID = new Hashtable();

    /** Table of global ID's for local classnames. (classname-to-globalID
        mappings) */
    public final static Hashtable classNameToGlobalID = new Hashtable();

    /** Pending. True if a propagation is pending. */
    public static boolean pending = false;

    /** Waiting. True if the FieldSend thread(s) are waiting. */
    public static boolean waiting = false;

    /** Background send thread. Propagates values as this thread is alerted
        to their alteration. */
    public void run(){

}
```

Annexure C

C1. TYPICAL PRIOR ART FINALIZATION FOR A SINGLE MACHINE:

```
Method finalize()
0 getstatic #9 <Field java.io.PrintStream out>
3 ldc #24 <String "Deleted...">
5 invokevirtual #16 <Method void println(java.lang.String)>
8 return
```

C2. PREFERRED FINALIZATION FOR MULTIPLE MACHINES

```
Method finalize()
0 invokestatic #3 <Method boolean isLastReference()>
3 ifne 7
6 return
7 getstatic #9 <Field java.io.PrintStream out>
```

10 ldc #24 <String "Deleted...">
12 invokevirtual #16 <Method void println(java.lang.String)>
15 return

C3. PREFERRED FINALIZATION FOR MULTIPLE MACHINES (Alternative)

Method finalize()
0 aload_0
1 invokestatic #3 <Method boolean isLastReference(java.lang.Object)>
4 ifne 8
7 return
8 getstatic #9 <Field java.io.PrintStream out>
11 ldc #24 <String "Deleted...">
13 invokevirtual #16 <Method void println(java.lang.String)>
16 return

Annexure C4

```
import java.lang.*;

public class example{

   /** Finalize method. */
   protected void finalize() throws Throwable{

      // "Deleted..." is printed out when this object is garbaged.
      System.out.println("Deleted...");

   }

}
```

CLAIMS

1. A multiple computer system having at least one application program running simultaneously on a plurality of computers interconnected by a communications network, wherein a like plurality of substantially identical objects are created, each in the corresponding computer and each having a substantially identical name, and wherein all said identical objects are collectively deleted when each one of said plurality of computers no longer needs to refer to their corresponding object.

2. The system as claimed in claim 1 wherein each said computer includes a distributed run time means with the distributed run time means of each said computer able to communicate with all other computers whereby if a portion of said application program(s) running on one of said computers no longer needs to refer to an object in that computer then the identity of the unreferenced object is transmitted by the distributed run time means of said one computer to a shared table accessible by all the other computers.

3. The system as claimed in claim 2 wherein each said application program is modified before, during, or after loading by inserting a finalization routine to modify each instance at which said application program no longer needs to refer to an object.

4. The system as claimed in claim 3 wherein the application program is modified in accordance with a procedure selected from the group of procedures consisting of re-compilation at loading, pre-compilation prior to loading, compilation prior to loading, just-in-time compilation, and re-compilation after loading and before execution of the relevant portion of application program.

5. The system as claimed in claim 2 wherein said modified application program is transferred to all said computers in accordance with a procedure selected from the group consisting of master/slave transfer, branched transfer and cascaded transfer.

6. A plurality of computers interconnected via a communications link and operating at least one application program simultaneously wherein each said computer in operating said at least one application program needs, or no longer needs to refer to an object only in local memory physically located in each said computer, the contents of the local memory utilized by each said computer is fundamentally similar but not, at each instant, identical, and every one of said computers has a finalization routine which deletes a non-referenced object only if each one of said plurality of computers no longer needs to refer to their corresponding object.

7. The plurality of computers as claimed in claim 6 wherein the local memory capacity allocated to the or each said application program is substantially identical and the total memory capacity available to the or each said application program is said allocated memory capacity.

8. The plurality of computers as claimed in claim 6 wherein all said distribution update means communicate via said communications link at a data transfer rate which is substantially less than the local memory read rate.

9. The plurality of computers as claimed in claim 6 wherein at least some of said computers are manufactured by different manufacturers and/or have different operating systems.

10. A method of running at least one application program on a plurality of computers simultaneously, said computers being interconnected by means of a communications network, said method comprising the steps of:
(i) creating a like plurality of substantially identical objects each in the corresponding computer and each having a substantially identical name, and
(ii) deleting all said identical objects collectively when all of said plurality of computers no longer need to refer to their corresponding object.

11. A method as claimed in claim 10 including the further step of:
(iii) providing each said computer with a distributed run time means to communicate between said computers via said communications network.

12. A method as claimed in claim 11 including the further step of:

(iv) providing a shared table accessible by each said distributed run time means and in which is stored the identity of any computer which no longer requires to access an object, together with the identity of the object.

13. A method as claimed in claim 12 including the further step of:

(v) associating a counter means with said shared table, said counter means storing a count of the number of said computers which no longer require to access said object.

14. A method as claimed in claim 13 including the further step of:

(vi) providing an additional computer on which said shared program does not run and which hosts said shared table and counter, said additional computer being connected to said communications network.

15. A method of ensuring consistent finalization of an application program to be run simultaneously on a plurality of computers interconnected via a communications network, said method comprising the steps of:

(i) scrutinizing said application program at, or prior to, or after loading to detect each program step defining an finalization routine, and

(ii) modifying said finalization routine to ensure collective deletion of corresponding objects in all said computers only when each one of said computers no longer needs to refer to their corresponding object.

16. The method claimed in claim 15 wherein step (ii) comprises the steps of:

(iii) loading and executing said finalization routine on one of said computers,

(iv) modifying said finalization routine by said one computer, and

(v) transferring said modified finalization routine to each of the remaining computers.

17. The method as claimed in claim 16 wherein said modified finalization routine is supplied by said one computer direct to each of said remaining computers.

18. The method as claimed in claim 16 wherein said modified finalization routine is supplied in cascade fashion from said one computer sequentially to each of said remaining computers.

19. The method claimed in claim 15 wherein step (ii) comprises the steps of:

(vi) loading and modifying said finalization routine on one of said computers,

(vii)said one computer sending said unmodified finalization routine to each of the remaining computers, and

(viii) each of said remaining computers modifying said finalization routine after receipt of same.

20. The method claimed in claim 19 wherein said unmodified finalization routine is supplied by said one computer directly to each of said remaining computers.

21. The method claimed in claim 19 wherein said unmodified finalization routine is supplied in cascade fashion from said one computer sequentially to each of said remaining computers.

22. The method as claimed in claim 15 including the further step of:

(ix) modifying said application program utilizing a procedure selected from the group of procedures consisting of re-compilation at loading, pre-compilation prior to loading, compilation prior to loading, just-in-time compilation, and re-compilation after loading and before execution of the relevant portion of application program.

23. The method as claimed in claim 15 including the further step of:

(x) transferring the modified application program to all said computers utilizing a procedure selected from the group consisting of master/slave transfer, branched transfer and cascaded transfer.

24. In a multiple thread processing computer operation in which individual threads of a single application program are simultaneously being processed each on a corresponding one of a plurality of computers interconnected via a communications link, and in which objects in local memory physically associated with the computer processing each thread have corresponding objects in the local memory of each other said computer, the improvement comprising collectively deleting all said corresponding objects when each

one of said plurality of computers no longer needs to refer to their corresponding object.

25. The improvement as claimed in claim 24 wherein an object residing in the memory associated with one said thread and to be deleted has its identity communicated by the computer of said one thread to a shared table accessable by all other said computers.

26. The improvement as claimed in claim 24 wherein an object residing in the memory associated with one said thread and to be deleted has its identity transmitted to the computer associated with another said thread and is transmitted thereby to a shared table accessable by all said other computers.

27. A computer program product comprising a set of program instructions stored in a storage medium and operable to permit a plurality of computers to carry out the method as claimed in claim 10 or 15.

28. A plurality of computers interconnected via a communication network and operable to ensure consistent initialization of an application program running simultaneously of said computers, said computers being programmed to carry out the method as claimed in claim 10 or 15 or being loaded with the computer program product as claimed in claim 26.

Int. Cl. [7]: G06F 15/16

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
DWPI, USPTO, PCT, IEEE, internet (object, replicate, redundant, mirror, cluster, distributed, lock, thread, compile, high availability, runtime, virtual machine, etc.)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	WO 2003/083614 A1 (ETERNAL SYSTEMS, INC.), 9 October 2003 the whole document	1-28
X	US 6,625,751 B1 (STAROVIC et al), 23 September 2003 the whole document	1-28
X	WO 2002/044835 A2 (GINGERICH), 6 June 2002 the whole document	1-28
X	US 2004/0073828 A1 (BRONSTEIN), 15 April 2004 the whole document	1-28

[X] Further documents are listed in the continuation of Box C [X] See patent family annex

* Special categories of cited documents:
"A" document defining the general state of the art which is not considered to be of particular relevance
"E" earlier application or patent but published on or after the international filing date
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
"O" document referring to an oral disclosure, use, exhibition or other means
"P" document published prior to the international filing date but later than the priority date claimed
"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"&" document member of the same patent family

Date of the actual completion of the international search	Date of mailing of the international search report
4 July 2005	11 JUL 2005
Name and mailing address of the ISA/AU	Authorized officer
AUSTRALIAN PATENT OFFICE PO BOX 200, WODEN ACT 2606, AUSTRALIA E-mail address: pct@ipaustralia.gov.au Facsimile No. (02) 6285 3929	MATTHEW HOLLINGWORTH Telephone No : (02) 6283 2024

Form PCT/ISA/210 (second sheet) (January 2004)

C (Continuation). DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US 5,488,723 A (BARADEL et al), 30 January 1996 the whole document	1-28
X	T. C. Bressoud, *TFT: A Software System for Application-Transparent Fault Tolerance* Proc. 28th Annual International Symposium on Fault-Tolerant Computing, p. 128-37, 1998	1-28

INTERNATIONAL SEARCH REPORT

Information on patent family members

International application No.
PCT/AU2005/000581

This Annex lists the known "A" publication level patent family members relating to the patent documents cited in the above-mentioned international search report. The Australian Patent Office is in no way liable for these particulars which are merely given for the purpose of information.

Patent Document Cited in Search Report		Patent Family Member					
WO	03083614	AU	2003223352	AU	2003230748	EP	1495414
		EP	1495571	US	2004078617	US	2004078618
		WO	03084116				
US	6625751	GB	2353113				
WO	0244835	AU	32411/02				
US	2004073828	NONE					
US	5488723	EP	0572307	FR	2691559	WO	9324884

Due to data integration issues this family listing may not include 10 digit Australian applications filed since May 2001.
